*“Practical Strategies for Emerging Energy Technologies”*

---

**Energy Policy = Choice of Fuel(s)**

**“Use What You Have!”**

# BP “Six Megatrends”

---

## 1. Energy transitions and the dominant fuel

- Over time the energy sector experiences major transitions. For centuries, wood was the dominant fuel, then coal and now oil. As the 21st century develops, gas is now growing faster than any other fossil fuel - and renewables faster still.
- With these changes in energy types, allied with sharp changes in prices, you have a complex scenario. The world is changing dramatically: from a supply and demand perspective, a geopolitical perspective and, importantly, from a climate policy perspective. **The 2015 Paris agreement**, which aims to keep the global temperature rise this century to well below 2°C, **will dictate the speed of these transitions.**

## 2. Oil supply

- Over the past two decades, the energy world has moved from a situation where oil supply would peak and decline, to a situation where oil is so plentiful it has driven prices sharply downwards. That means a change in thinking is needed.
- **The focus is now much more around peak oil from a demand side**; that there will be a period when demand for oil will peak and then gradually start to decline. Broad consensus suggests that this ‘peak oil’ window is most probably somewhere between 2025 and 2040, but there is considerable uncertainty surrounding this.

## 3. Gas supply

- Natural gas resembles oil in being plentiful but differs in being used mainly for power and industry rather than transport. It has also tended to be traded within regions rather than across a single global market. However, this is changing - the amount of natural **gas traded across borders is increasing as liquefied natural gas (LNG)** surpasses pipeline imports as the dominant form of traded gas in the next 20 years.
- As with oil, there is a lot of gas available very cheaply. Nowhere in our **demand forecasts for the next few decades do we see gas peaking**, unlike oil. Of course, from a carbon perspective, it has half the CO<sub>2</sub> emissions of coal when burnt to produce power.

# BP Six Megatrends

---

## 4. Growth of renewables

- BP is preparing for a world where power comes increasingly from renewable sources. Wind and solar power have been growing faster than fossil fuels, though from a low base and with the benefit of government subsidies in many regions. Now, in many situations, they are becoming competitive with fossil fuels and are poised to deliver substantial shares of energy.
- The growth of renewables has exceeded pretty much all forecasts. There has been double-digit growth for wind and solar in the past few years and because the manufacturing costs have come down as well, cost reductions have been about 80% in solar and about 50% in wind. However, what that **ignores is the cost of intermittency** because, of course, the sun does not shine all the time and the wind does not blow all the time. Therefore, in many places the existing grid and the existing fossil system are used to back up supply when energy from renewables is not available.

## 5. Electrification

- **The transport sector is set to change significantly, with electric vehicles, driverless - or autonomous - vehicles and new types of business.**
- I think there is no forecast anywhere that does not expect demand for electricity to grow and for electricity to become a more important part of the energy mix. There is also a sort of consumer desirability for newer electric vehicles, like the current Teslas, the new Tesla Model 3 that will be coming out at a much more competitive price and the BMW i8.
- I think the interesting area is the combination of vehicle electrification with new methods of mobility, car-pooling and ride-sharing such as we are seeing with the likes of Hailo and Uber. And the impact of vehicle autonomy could be enormous but the uncertainty range is large

## 6. Changes in demand

- The demographics of emerging economies and the demands of millennials - those born post-1980 - are likely to change consumption and work patterns. In the older economies, patterns of demand are changing with the generations. There is virtually no energy growth in the OECD (Organization for Economic Cooperation and Development) countries, particularly because of efficiency gains.
- Strong economic growth will mean the **emerging economies** - the non-OECD countries - **are likely to account for nearly all of the energy growth** in the coming decades.

# The Big Picture: World Industrial Power Prices

## THE BIG PICTURE: World Industrial Power Prices

How much industry pays for power varies tremendously by country, owing to variations in generation costs, network costs, and taxes, fees, and surcharges. This comparison shows average industrial electricity prices in 2013, with each nation's tax component. Also shown is the fuel source that dominated each nation's power mix in 2013. *Source: UK Department of Energy and Climate Change, Eurostat, International Energy Agency —Copy and artwork by Sonal Patel, associate editor*

# Power – “Still in the Dark”

1.2 billion people  
17% of Global  
Population do not  
have access to  
electricity

GLOBAL MONITOR

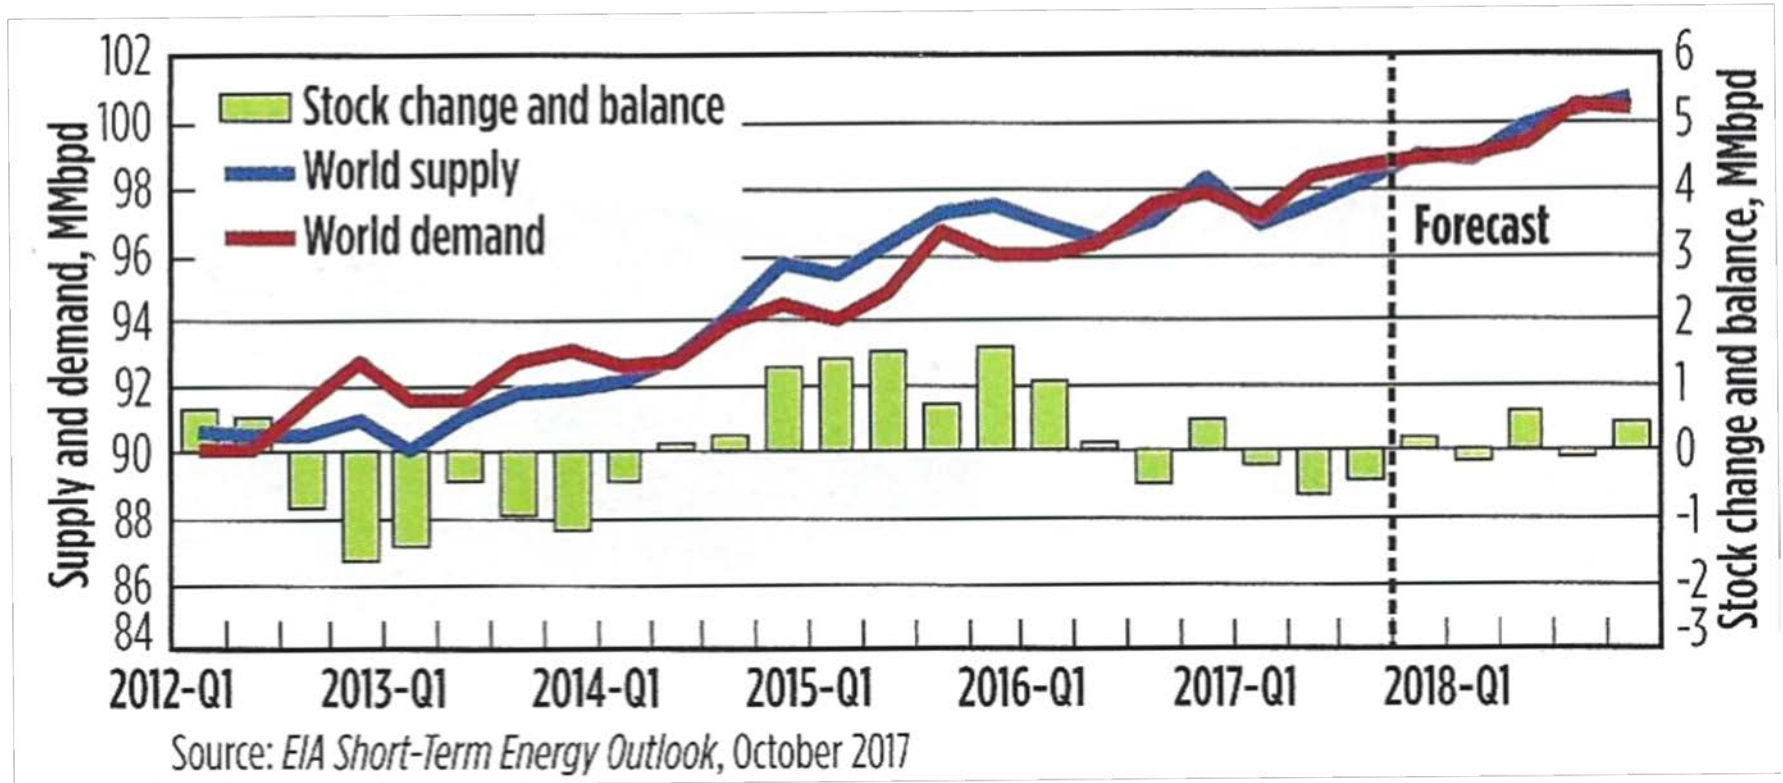

## THE BIG PICTURE: Still in the Dark

An estimated 1.2 billion people—17% of the global population—did not have access to electricity in 2013, the latest data from the International Energy Agency show. More than 95% of those living without electricity are in countries in sub-Saharan Africa and developing Asia, and they are predominantly in rural areas (around 80% of the world total). Here are five countries per region (developing Asia, Africa, Latin America, and the Middle East) that have the largest populations without access to electricity. Also noted is that country's national electrification rate (%). Source: IEA, World Energy Outlook 2015

# Global Liquids Cost Curve - 2015

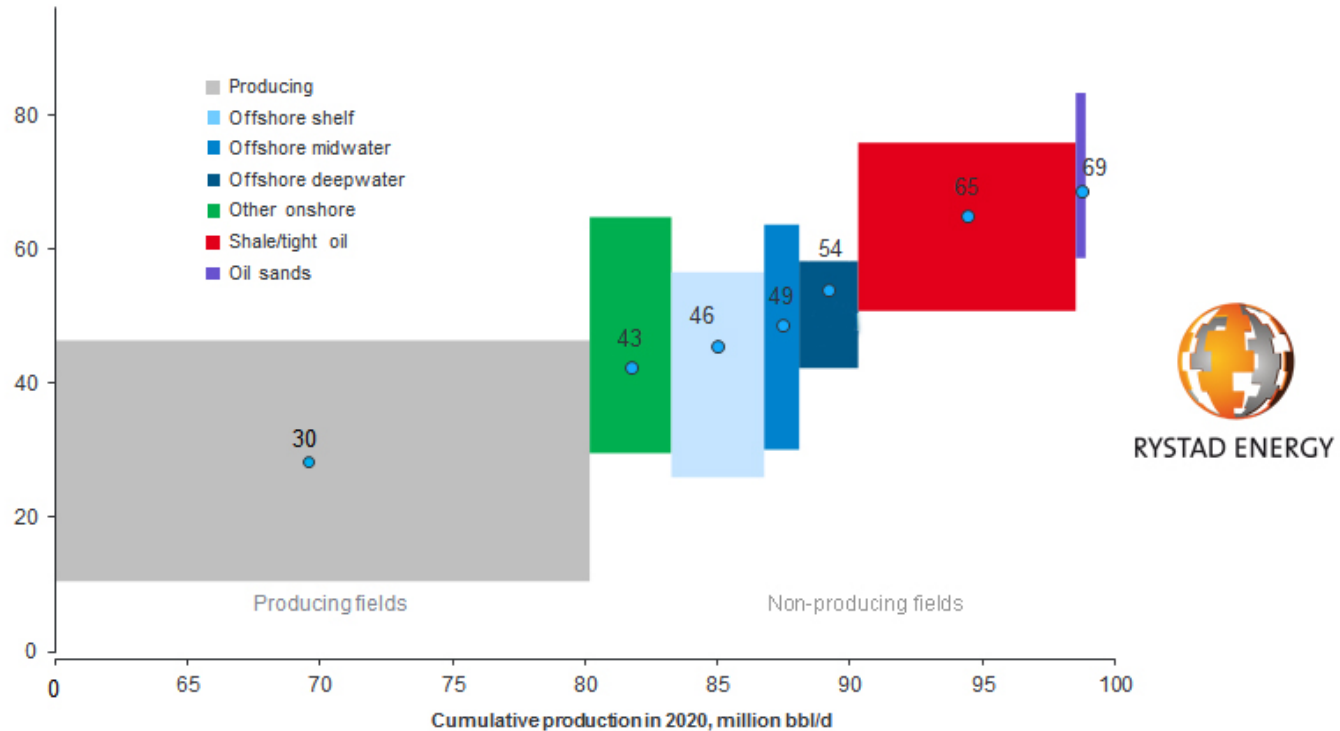

GLOBAL LIQUIDS COST CURVE\*  
Real Brent USD/bbl

\*The break-even price is the Brent oil price at which NPV equals zero using a real discount rate of 7.5%. Resources are split into two life cycle categories: producing and non-producing (under development and discoveries). The latter is further split into several supply segment groups. The curve is made up of more than 20,000 unique assets based on each asset's break-even price and remaining liquids resources in 2015. Source: Rystad Energy UCube September 2015

# Global Liquids Cost Curve - 2016

**Global liquids cost curve**  
Brent-equivalent breakeven oil price, USD/bbl

Producing fields are the cheapest supply source, as opposed to the most expensive – non producing oil sands – with 69 USD/bbl. The producing fields' low breakeven price is due to past capex that we consider as sunk, cheap Middle East and shale production. Non-producing shale and oil sands are the marginal sources of supply in 2020, with high drilling/completion costs for the former and high capex/opex for the latter.

Rystad Energy's liquids cost curve is made up of nearly 20,000 unique assets by considering each asset's breakeven oil price and potential production in 2020. The breakeven price is the Brent oil price at which NPV equals zero, considering all future cash flows using a real discount rate of 7.5%.

# World Energy Balance

# U.S. 2016 Energy Flow – 97.3Quads

Estimated U.S. Energy Consumption in 2016: 97.3 Quads

“This year marks two changes to the energy flow chart. The Energy Information Administration has changed the way it analyzes and reports renewable energy use, and those changes are reflected in the 2016 chart as well as a revision to the 2015 analysis. Additionally, the estimate of efficiency of the industrial sector has been reduced from 80 percent to 49 percent to align with recent analysis at the DOE’s Advanced Manufacturing Office. LLNL reports all year-over-year changes on a consistent basis with the new methodology.”

“Practical Strategies for Emerging Energy Technologies”

# Oil Share of Total Energy Demand

Alessandro Blasi  
Lead Programme Manager - Economics and Investment Department  
Executive Office of International Energy Agency  
IEA World Energy Outlook 2017

# Coal Consumption – 3839.9 Mtoe

- Coal consumption declined by 1.8% in 2015
- India grew by 10.6%
- China declined by 1.5%
- Asia represents 72.9% of 2015

As of March 1, 2016.

Includes coal production for bankrupt coal companies as operator, owner and ultimate owner of mines that have filed bankruptcy since 2012.

\* Mines in bankruptcy are defined as mines owned by companies in bankruptcy since 2012 as tracked by S&P Global Market Intelligence compared to ownership and production data from the U.S. Mine Safety and Health Administration as of the end of the fourth quarter of 2015. Some mines may have since been transferred to solvent companies and some companies may have since emerged from bankruptcy.

<sup>1</sup> Peabody Energy Corp.; Northern Illinois Municipal; Kentucky Muni Power Agency; Southern Illinois Power Coop; Prairie Power Inc.; MJMEUC; Indiana Municipal Power Agency; Illinois Municipal Elec Agency; American Mun Power Inc.

Source: S&P Global Market Intelligence

- 44.3% of the coal produced in the U.S. came from a company that has filed for bankruptcy court protection since 2012.
- More than 69% of the coal produced in the Powder River Basin came from coal companies recently filing bankruptcy.
- Three of every four tons mined in Wyoming came from a coal company on the bankruptcy list.
- 28.9% of coal from the Illinois Basin comes from a coal company recently filing for bankruptcy court protections.

## Q4'15 coal production by major coal basins

Coal basin	Coal produced (tons)		
	Total	From mines of companies recently in bankruptcy*	% production from companies recently in bankruptcy*
Powder River Basin	98,013,293	68,084,346	69.46
Illinois Basin	26,410,510	7,628,394	28.88
Northern Appalachia	27,356,159	3,772,808	13.79
Central Appalachia	18,699,925	6,364,752	34.04
Entire U.S.	207,355,826	91,946,261	44.34

# What does “450 ppm(v) CO<sub>2</sub>” Mean?

Gas	Ratio compared to Dry Air (%)		Molecular Mass - M - (kg/kmol)	Chemical Symbol
	By volume	By weight		
Oxygen	20.9500	23.2	32.00	O <sub>2</sub>
Nitrogen	78.0900	75.47	28.02	N <sub>2</sub>
Carbon Dioxide	0.0300	0.046	44.01	CO <sub>2</sub>
Hydrogen	0.0001	~ 0	2.02	H <sub>2</sub>
Argon	0.9330	1.28	39.94	Ar
Neon	0.0018	0.0012	20.18	Ne
Helium	0.0005	0.00007	4.00	He
Krypton	0.0001	0.0003	83.80	Kr
Xenon	9 10 <sup>-6</sup>	0.00004	131.29	Xe

Standard assumptions on the chemical composition of Air

$$0.0300\% = 300 \text{ ppm(v)}$$

Value July 2016 at Mauna Loa was 404.30ppm(v)

# Recent Monthly Mean CO<sub>2</sub> at Mauna Loa

March 2017: 407.18 ppm  
March 2016: 404.83 ppm

Last updated: April 5, 2017

# CO<sub>2</sub> Emission from the Power Sector

## - CO<sub>2</sub> emissions from electricity generation

- 2,416 million metric tonnes in 2005
- 1,925 million metric tonnes in 2015 = (20.3%)
- 1,643 million metric tonnes in 2030 = (32.0% lower than 2005)

Note:  
2005 was close to the  
all time high

## - The Clean Power Plan - CPP

- A shift on the electricity generation mix, with generation from natural gas and renewables displacing coal-fired power, drove the reductions in emissions.
- Total carbon dioxide emissions from the electric power sector declined even as demand for electricity remained relatively flat over the previous decade

# CO<sub>2</sub> Emission from Electric Power

Electric power sector carbon dioxide emissions, 1990, 2005, 2008, and 2009

	1990	2005	2008	2009
Estimated emissions (million metric tons)	1,831.0	2,416.9	2,373.7	2,160.3
Change from 1990 (million metric tons)		585.8	542.7	329.3
(percent)		32.0%	29.6%	18.0%
Average annual change from 1990 (percent)		1.9%	1.5%	0.9%
Change from 2005 (million metric tons)			-43.1	-256.5
(percent)			-1.8%	-10.6%
Change from 2008 (million metric tons)				-213.4
(percent)				-9.0%

Figure 15. U.S. electric power sector energy sales and losses and carbon dioxide emissions from primary fuel combustion, 1990-2009

**“32% reduction in 2005 power plant CO<sub>2</sub> emissions by 2030”**

**What does that really mean?  
It’s time for those pesky numbers again!**

# How the Clean Power Plan Works

---

- The Clean Air Act creates a partnership between EPA, states, tribes and U.S. territories – with EPA setting a goal and states and tribes choosing how they will meet it.
- **The final Clean Power Plan follows that approach. EPA is establishing interim and final carbon dioxide (CO<sub>2</sub>) emission performance rates for two subcategories of fossil fuel-fired electric generating units (EGUs):**
  - Fossil fuel-fired electric steam generating units (generally, coal- and oil-fired power plants)
  - Natural gas-fired combined cycle generating units
- To maximize the range of choices available to states in implementing the standards and to utilities in meeting them, EPA is establishing interim and final statewide goals in three forms:
  - A rate-based state goal measured in pounds per megawatt hour (lb/MWh);
  - A mass-based state goal measured in total short tons of CO<sub>2</sub>;
  - A mass-based state goal with a new source complement measured in total short tons of CO<sub>2</sub>.
- **States then develop and implement plans** that ensure that the power plants in their state – either individually, together or in combination with other measures – achieve the interim CO<sub>2</sub> emissions performance rates over the period of 2022 to 2029 and the final CO<sub>2</sub> emission performance rates, rate-based goals or mass-based goals by 2030.
- These final guidelines are consistent with the law and align with the approach that Congress and EPA have always taken to regulate emissions from this and all other industrial sectors – setting source-level, source category-wide standards that sources can meet through a variety of technologies and measures.

EPA State Goals appear to be based on 70% Natural Gas and 30% Renewables

# The window for action is rapidly closing

65% of our carbon budget compatible with a 2°C goal already used

We don't hear much about this number

GHG emissions

# The Carbon Conundrum

## The Carbon Capture Conundrum

Climate strategists are counting on carbon capture and storage. But can the technology meet its deadlines?

### Current trajectory 58 gigatons

This projection assumes that essentially no action is taken to address climate change. Models predict a long-term global temperature rise of 6 °C in such a scenario.

### Global pledges 40 gigatons

If countries make good on their pledges to reduce emissions, the projected trajectory is much less steep. Models suggest a long-term global temperature rise of 4 °C.

### Target 16 gigatons

Models associate this trajectory with a long-term global temperature rise no higher than 2 °C. That has been a long-standing goal in climate change negotiations.

### Scenarios and CCS targets for the three highest-emitting countries (in gigatons)

**Figure 3 | Contributions of different factors to the decline in US CO<sub>2</sub> emissions 2007-2009 and 2009-2011 and 2011-2013.** Between 2007 and 2009, decreases in the volume of goods and services consumed during the economic recession (red) was the primary contributor to the nearly 10% drop in emissions. But between 2009 and 2011, consumption (consump.) volume rebounded, population grew and the energy intensity of output increased, driving up emissions by 1.3% against modest decreases in the carbon intensity of the fuel mix and shifts in production structure and consumption patterns. Between 2011 and 2013, increases in population and consumption volume again pushed emissions upward, but overall emissions decreased by 2.1% due to further changes in production (prod.) structure, consumption patterns, decreasing use of coal and decreases in energy intensity of output. Not shown here, emissions increased by 1.7% between 2012 and 2013, driven primarily by increases in consumption volume.

**base**<sub>e</sub>

**“The new EPA Clean Power Plan is largely built on fuel switching and renewables deployment”**

# Gas Bridge to Renewables Already Built

---

- For the U.S. to reach its climate goals, the deadline for constructing the last gas-fired power plant is coming up shortly — if not already past
- Gas has a significant near-term role in reducing dependence on coal-fired power and helping the transition to intermittent renewable sources. But, to reduce greenhouse gas emissions to a target of 80% below 1990 levels by 2050, the nation must ultimately eliminate almost all use of fossil fuels, including natural gas
- "A power plant on the drawing boards today could still be operational in 2050 and well beyond. With each passing year, the likely life span of new natural gas power plants moves further beyond 2050 "
- **The U.S. EPA's Clean Power Plan might do more harm than good** because substituting gas-fired power for coal capacity is one of the options for complying with the rules requirements. Rather, lawmakers should consider setting a final date beyond which no new natural gas power plants can be approved, Weissman advised.
- To make that possible while maintaining grid reliability, policymakers would have to require strategic adoption of renewable power, trying to match the types and locations for maximum impact.
- Lawmakers and regulators would also need to deploy a wide range of demand-response tools, focus on energy efficiency measures and better structure regional power markets to manage shifting demand.
- Almost 237 GW of gas-fired generation capacity was added between 2000 and 2010, making up 81% of all the generation capacity added in that decade. This momentum could increasingly complicate efforts to cut back on gas use.
- **"As more people and institutions invest in natural gas, political pressure to sustain its use grows. It will become more and more difficult to achieve long-range greenhouse gas reduction goals". "Natural gas cannot play a long-term role in creating our desired carbon-constrained future, as its benefits are not enough to support our carbon reduction goals"**

Steve Weissman – Senior Policy Advisor, Center for Sustainable Energy

“Practical Strategies for Emerging Energy Technologies”

# EIA 2017 International Energy Outlook

## The Carbon Capture Conundrum

Climate strategists are counting on carbon capture and storage. But can the technology meet its deadlines?

### Current trajectory 58 gigatons

This projection assumes that essentially no action is taken to address climate change. Models predict a long-term global temperature rise of 6 °C in such a scenario.

### Global pledges 40 gigatons

If countries make good on their pledges to reduce emissions, the projected trajectory is much less steep. Models suggest a long-term global temperature rise of 4 °C.

### Target 16 gigatons

Models associate this trajectory with a long-term global temperature rise no higher than 2 °C. That has been a long-standing goal in climate change negotiations.

### Scenarios and CCS targets for the three highest-emitting countries (in gigatons)

### EIA 2017 International Energy Outlook

U.S. w/CPP 5.072 Gt  
U.S. w/o CPP 5.554 Gt

“Practical Strategies for Emerging Energy Technologies”

# Making Electricity - The Terminology

---

- **Prime Movers** extract power from energy level differentials
  - Sources are the high side
  - Sinks are the low side
- Most Prime Movers are **Heat Engines**
- **Working Fluids** are the media used to
  - Extract the heat from the source/high side at a high pressure & temperature
  - Expand thru the Prime Mover, causing equipment rotation
  - Recover remaining heat & pressure on the low side
    - Return Working Fluid to the system a **closed cycle**
    - Exhaust Working Fluid to the atmosphere in an **open cycle**
- The prime mover drives
  - An Electric Generator, or
  - Mechanical devices such as compressor and pumps
- The higher the energy differentials , the smaller the equipment
- The smaller the equipment the faster it runs and the lower the cost
- The equipment used in heat cycles are
  - Turbines
  - Reciprocating engines
  - The equipment used in heat cycles are
- **Cycle Efficiency** improves with greater high side pressure and temperature

# Working Fluids

---

## - Steam

- Supercritical (SCPC)
- Ultra-supercritical Pulverized Coal (USCPC)
- Nuclear
- Geothermal
- Concentrated Solar

## - Air/Vitiated Air

- Gas Turbine
- Wind Turbine

## - Organic Fluid

- Organic Rankine Cycle (ORC)
- Ocean Thermal–Ammonia
- Geothermal

## Water

- Hydroelectric
- Wave
- Tidal

## - Helium

- Pebble Bed Modular Reactor (PBMR)
- Molten Salt Reactor (MSR)

## - CO<sub>2</sub>

- Allam Cycle
- Molten Salt Reactor
- Super-critical CO<sub>2</sub>

# Units of Measure

---

## Units of Mass

- Ton (short) = 2000 lb
- tonne (metric) = 1000 kg = 2205 lb
- Mt = mmt = million metric tonnes
- Gigatonne (Gt) = 1000 Mt

## Units of Cost

- Plant Cost (\$/kW)
- LCOE – Levelized Cost of Electricity (mils/kWh)

## Utilization Rate

- Capacity Factor % = kWh produced/kWh rated
  - 85% Pulverized Coal
  - 75% NGCC
  - 20-30% Wind

## Measures of Efficiency

- Power Plant Heat Rate
  - Btu/kWh
- Power Plant Efficiency
  - 3412 Btu/kWh/Plant Heat Rate
- LHV & HHV Fuel Heat Content
  - The gas company sells HHV
  - Utilities normally use HHV
  - Gas Turbine Industry advertises/uses LLV
  - Natural Gas
    - LHV = 23,860 Btu/lb
    - HHV = 21,501 Btu/lb
  - The effect is a 10% difference in claimed efficiency
- Net Output vs. Gross Output

### Each fuel has:

- An energy content - Btu/lb
  - A carbon content – lb-CO<sub>2</sub>/mmBtu
- Each Power Plant (type) has efficiency or “heat rate” – Btu/kWh

# Hydrocarbon Fuels Energy Content

Energy Source	Unit	Energy Content (Btu)	Btu/lb
Electricity	1 Kilowatt-hour	3412	-
Butane	1 Cubic Foot (cu.ft.)	3200	20,185
Coal	1 Ton	28000000	14,000
Crude Oil	1 Barrel - 42 gallons	5800000	19,153

Conventional Combustion Turbine	85	888	971	10450	21501	116.38	1216

CCS Required  
CCS Not Required

- Coal with CCS
  - First Cost \$/kW is ~5x
  - Levelized Cost of Electricity is 2.3x
  - Efficiency is ~1/2
  - w/Natural Gas at \$6.13

Plant Type	Plant Cost (2012\$/kW)	
	Without CCS	With CCS
Single Advanced Pulverized Coal	\$3,246	\$5,227
Dual Advanced Pulverized Coal	\$2,934	\$4,724
Single IGCC	\$4,400	\$6,599
Advanced Combined Cycle	\$1,023	\$2,095

# McKinsey CO<sub>2</sub> Cost Curve V1.0

Global cost curve for greenhouse gas abatement measures beyond 'business as usual'; greenhouse gases measured in GtCO<sub>2</sub>e<sup>1</sup>

● Approximate abatement required beyond 'business as usual,' 2030

<sup>1</sup>GtCO<sub>2</sub>e = gigaton of carbon dioxide equivalent; "business as usual" based on emissions growth driven mainly by increasing demand for energy and transport around the world and by tropical deforestation.

<sup>2</sup>tCO<sub>2</sub>e = ton of carbon dioxide equivalent.

<sup>3</sup>Measures costing more than €40 a ton were not the focus of this study.

<sup>4</sup>Atmospheric concentration of all greenhouse gases recalculated into CO<sub>2</sub> equivalents; ppm = parts per million.

<sup>5</sup>Marginal cost of avoiding emissions of 1 ton of CO<sub>2</sub> equivalents in each abatement demand scenario.

# McKinsey Global GHG Cost Curve V2.1

Note: The curve presents an estimate of the maximum potential of all technical GHG abatement measures below €80 per tCO<sub>2</sub>e if each lever was pursued aggressively. It is not a forecast of what role different abatement measures and technologies will play.

# BP Conversion Factors

## Approximate conversion factors

### Crude oil\*

From	To				
	tonnes (metric)	kilolitres	barrels	US gallons	tonnes per year
	<b>Multiply by</b>				
Tonnes (metric)	1	1.165	7.33	307.86	-
Kilolitres	0.8581	1	6.2898	264.17	-
Barrels	0.1364	0.159	1	42	-
US gallons	0.00325	0.0038	0.0238	1	-
Barrels per day	-	-	-	-	49.8

\*Based on worldwide average gravity.

### Products

	To convert			
	barrels to tonnes	tonnes to barrels	kilolitres to tonnes	tonnes to kilolitres
	<b>Multiply by</b>			
Liquefied petroleum gas (LPG)	0.086	11.60	0.542	1.844
Gasoline	0.120	8.35	0.753	1.328
Kerosene	0.127	7.88	0.798	1.253
Gas oil/diesel	0.134	7.46	0.843	1.186
Residual fuel oil	0.157	6.35	0.991	1.010
Product basket	0.125	7.98	0.788	1.269

### Natural gas (NG) and liquefied natural gas (LNG)

From	To					
	billion cubic metres NG	billion cubic feet NG	million tonnes oil equivalent	million tonnes LNG	trillion British thermal units	million barrels oil equivalent
	<b>Multiply by</b>					
1 billion cubic metres NG	1	35.3	0.90	0.74	35.7	6.60
1 billion cubic feet NG	0.028	1	0.025	0.021	1.01	0.19
1 million tonnes oil equivalent	1.11	39.2	1	0.82	39.7	7.33
1 million tonnes LNG	1.36	48.0	1.22	1	48.6	8.97
1 trillion British thermal units	0.028	0.99	0.025	0.021	1	0.18
1 million barrels oil equivalent	0.15	5.35	0.14	0.11	5.41	1

### Units

1 metric tonne	= 2204.62lb
	= 1.1023 short tons
1 kilolitre	= 6.2898 barrels
	= 1 cubic metre
1 kilocalorie (kcal)	= 4.187kJ
	= 3.968Btu
1 kilojoule (kJ)	= 0.239kcal
	= 0.948Btu
1 British thermal unit (Btu)	= 0.252kcal
	= 1.055kJ
1 kilowatt-hour (kWh)	= 860kcal
	= 3600kJ
	= 3412Btu

### Calorific equivalents

One tonne of oil equivalent equals approximately:

Heat units	10 million kilocalories
	42 gigajoules
	40 million British thermal units
Solid fuels	1.5 tonnes of hard coal
	3 tonnes of lignite
Gaseous fuels	See Natural gas and liquefied natural gas table
Electricity	12 megawatt-hours

One million tonnes of oil or oil equivalent produces about 4400 gigawatt-hours (= 4.4 terawatt-hours) of electricity in a modern power station.

1 barrel of ethanol = 0.57 barrel of oil  
1 barrel of biodiesel = 0.88 barrel of oil
